Abstract

The Traffic World is an action domain proposed by Erik Sandewall as part of his Logic Modelling Workshop. The Causal Calculator (CCALC) is an implementation of a nonmonotonic causal logic. We show how to represent the Traffic World in the input language of CCALC, and how to use CCALC to test this representation.

1 Introduction

The Traffic World is an action domain proposed by Erik Sandewall as part of his Logic Modelling Workshop[1]. We show how to represent this domain in the input language of the Causal Calculator (CCALC)[2]—an implementation of the nonmonotonic causal logic from [Giunchiglia *et al.*, 2001]. A representation of another Workshop domain—the Zoo World—in the same language is discussed in [Lee *et al.*, 2001]. We assume that the reader is familiar with some parts of [Giunchiglia *et al.*, 2001]: with the definition of nonmonotonic causal theories in Sections 2.1–2.3, with the definition of action language $\mathcal{C}+$ in Section 4.2, and with the discussion of the syntax of the input language of CCALC in the appendix.

The next section contains an extensive quote from the Logic Modelling Workshop description of the Traffic World. Then we discuss the possibility of describing continuous motion using integer arithmetic (Section 3) and the use of action languages for representing change in the absence of actions (Section 4). After a brief discussion of the language of CCALC (Section 5), our formalization of the Traffic World is presented in Section 6. Examples of the use of CCALC for testing the formalization are shown in Section 7. Finally, Section 8 compares our approach to the Traffic World with related work.

2 Sandewall's Description of the Traffic World

Here is the Logic Modelling Workshop description that we want to formalize:

> The TRAFFIC scenario world is intended to capture simple hybrid phenomena: vehicles moving continuously with well defined velocities along roads with well defined lengths, respecting speed limits and other restrictions on the vehicle's behaviors.
>
> The landscape in the TRAFFIC Scenario World uses the following two types:
>
> - *Nodes*, which can be thought of as road crossings without any particular structure (no lanes, etc)
> - *Segments*, which can be thought of as road segments each of which connects two nodes.
>
> The set of nodes and the set of segments are both considered as fully known, and all nodes and segments can be assigned individual names.
>
> Each segment has exactly one *start node* and exactly one *end node*. It also has a *length*, which is a real number (or rational number, if preferred). This is all the structure there is.
>
> ...The activity structure in the TRAFFIC world uses only one sort:
>
> - *Cars*, which are intuitively thought of as driving along the arcs in the TRAFFIC landscape structure.
>
> Each car has a *position* at each point in time. The position is indicated as a pair consisting of the segment where the car is located, and the distance travelled along the segment. The distance travelled is a number between 0 and the segment's length.
>
> Each car has a *top speed*, and each road segment has a *speed limit*. The actual velocity of a car at each point in time is the maximum velocity allowed by the following three conditions:
>
> - The speed limit of the road segment where it is driving
> - Its own top speed
> - Surrounding traffic restrictions
>
> Cars drive at piecewise constant velocity, and can change velocity discontinuously. (A more refined variant, TRAFFIC2, will require cars to change their velocity continuously, and assumes piecewise constant acceleration/deceleration). When a car arrives at a node ("intersection") then it may continue on any segment that connects to that node, except the one it is arriving at.

> Cars can drive in both "directions" along a segment, that is, they can move both from the start node to the end node, and vice versa.
>
> Cars can not overtake — if two cars go in the same direction on the same road segment, and one catches up with the other, then it has to stay behind at least until they arrive to the next node, where possibly the second car can choose another direction onwards. Cars going in opposite directions on the same segment can meet without difficulty, however.
>
> The surrounding traffic restriction says that a car is never allowed to be closer than a fixed safety distance *varsigma* to the car in front of it, and it may never get itself into a situation where that could happen. This means, first of all, that when it gets to a distance of *varsigma* to a car moving in front of it on the same segment and in the same direction, then it must reduce speed to match the speed of the car in front of it. Also when getting close to a node (= an intersection), a car must reduce its speed in a way that takes into consideration all other cars that are just approaching or leaving the same node.

3 Continuous Motion and Integer Arithmetic

Under some special circumstances, questions about continuous motion can be discussed using integers, without ever mentioning reals or even rational numbers. Such special circumstances are assumed in our formalization of the Traffic World. Specifically, we assume that

- the lengths of all road segments and the safety distance *varsigma* are expressed by integers,
- the top speeds of all cars and the speed limits on all road segments are expressed by integers,
- in the scenarios under consideration, the times when cars leave and reach endpoints of road segments, and the times at which the distance between two cars traveling on the same segment in the same direction becomes *varsigma* are expressed by integers.

These constraints are similar to those adopted in the description of the spacecraft Integer in [Lee and Lifschitz, 2001]:

> Far away from stars and planets, the Integer is not affected by any external forces. As its proud name suggests, the mass of the spacecraft is an integer. For every integer t, the coordinates and all three components of the Integer's velocity vector at time t are integers; the forces applied to the spacecraft by its jet engines over the interval $(t, t+1)$, for any integer t, are constant vectors

whose components are integers as well. If the crew of the Integer attempts to violate any of these conditions, the jets will fail to operate!

The spacecraft Integer is actually close to the refined version of the Traffic World mentioned in Section 2 above, in the sense that its velocity changes continuously, and its acceleration is piecewise constant.

For query answering on the basis of our formalization of the Traffic World, it is essential that all time instants mentioned in the queries be expressed by integers.

Assumptions like these make it easier to describe motion in the action languages whose semantics is defined in the framework of transition systems [Gelfond and Lifschitz, 1998]. The use of these languages for describing motion without such simplifying assumptions is a topic for future research.

4 Change in the Absence of Actions

In our formalization of the Traffic World, the action of selecting a new road segment when a car reaches an intersection is denoted by $ChooseSegment(c, sg)$—the driver of car c chooses to turn into road segment sg.

Recall that in $\mathcal{C}+$ direct effects of actions are described by "dynamic laws" — expressions of the form

$$\textbf{caused } F \textbf{ if } G \textbf{ after } H$$

where F, G and H are formulas [Giunchiglia *et al.*, 2001, Section 4.2]. The logical constant $\top$ often plays the role of G, in which case the part **if** G can be dropped:

$$\textbf{caused } F \textbf{ after } H.$$

The expression

$$ChooseSegment(c, sg) \textbf{ causes } NextSegment(c) = sg$$

describing the effect of the action $ChooseSegment(c, sg)$ in our formalization of the Traffic World, is shorthand for the dynamic law

$$\textbf{caused } NextSegment(c) = sg \textbf{ after } ChooseSegment(c, sg).$$

These actions of selecting a new road segment when a car reaches an intersection are actually the only actions performed in the Traffic World. Between intersections every car is assumed to be moving at the maximum speed allowed by the road conditions, so that the drivers are not permitted to perform any actions affecting the speeds of their cars.

The speeds of cars may change many times, however, during a time interval that does not include the execution of actions. Consider, for instance, a long road segment with a high speed limit, and two cars moving along it in the same direction. If the top

speed of the car in front is lower than the top speed of the second car then the latter will slow down at some point to match the speed of the slower car. If there are several cars on the road moving in the same direction then the surrounding traffic restriction may force the last of them to reduce its speed several times, although no actions will be executed. (An example of such a scenario is shown in Section 7.)

A similar phenomenon will be observed when several cars have simultaneously (or almost simultaneously) approached the same node from different directions, with the intention to turn into the same road. The cars will have to leave the intersection one by one, after the intervals that will guarantee the safety distance between them. In our formalization, there are no rules determining the order in which the cars are going to depart. This nondeterministic sequence of events may take a long time, and it does not involve the execution of actions.

Change in the absence of actions, so essential in the Traffic World, can be described in $\mathcal{C}+$ using dynamic laws that do not contain action symbols. For instance, the dynamic law

$$\begin{array}{l}\textbf{caused } \mathit{Distance}(c) = \mathit{ds} + \mathit{sp} \\ \qquad\qquad \textbf{after } \neg \mathit{WillLeave}(c) \wedge \mathit{Distance}(c) = \mathit{ds} \wedge \mathit{Speed}(c) = \mathit{sp}\end{array}$$

says that if (i) car c is going to remain on the same road segment during the next time interval, (ii) the distance travelled by c along that segment so far is ds, and (iii) the speed of c during that time interval is going to be equal to sp, then by the end of the time interval the distance travelled by c along the current road segment will become $ds + sp$.

5 Language of the Causal Calculator

As mentioned in the introduction, we assume that the reader is familiar with some parts of the companion paper [Giunchiglia *et al.*, 2001]. The following information about the language of CCALC will also be useful.

1. Abbreviations **constraint** and **exogenous** are defined in [Giunchiglia *et al.*, 2001, Section 4.3].

2. The ASCII representations of some symbols used in the language of CCALC are summarized in the following chart:

Symbol	$\neg$	$\neq$	$\wedge$	$\vee$	$\supset$	$\equiv$	$\bot$	$\top$
ASCII representation	`-`	`<>`	`&`	`++`	`->>`	`<->`	`false`	`true`

Encoding multiple conjunctions and disjunctions by ASCII characters can be illustrated by this example:

$$\bigwedge_{sg} \neg \mathit{ChooseSegment}(c, sg)$$

is written in CCALC as

```
[/\Sg | -chooseSegment(C,Sg)].
```

3. If a sort name is composed by adding a * to the name of a previously declared sort, this means that the set of objects of that sort consists of the objects of the previously declared sort and the auxiliary symbol none. These "*-sorts" are used for declaring partial valued fluents and are not explicitly declared as sorts.

For instance, assume that the objects of sort node are a and b:

```
:- sorts
  a, b          :: node.
```

Then the objects of sort node* will be a, b and none. This sort is useful when we want to talk about the node at which a car currently is,

```
:- constants
  node(car)     :: sdFluent(node*).
```

which may be none if the car is in the middle of a segment.

4. In the example above, note that the fluent node is declared as an sdFluent. This stands for "statically determined fluent"; see [Giunchiglia *et al.*, 2001, Sections 4.1, 4.2].

6 Formalization

Our formalization of the Traffic World is shown below and is available online[3].

We distinguish between the general assumptions about the Traffic World quoted in Section 2 above and specific details, such as the number and positions of road segments, the numerical values of their speed limits, the number of cars and their top speeds. Here we formalize only the general assumptions, and leave such details unspecified, as in the formalization of the Zoo World in [Lee *et al.*, 2001, Section 5]. A description of a specific scenario has to be added to our formalization to get an input file accepted by CCALC.

The annotation (lmw) found in many comments below refers to the Logic Modelling Workshop description of the Traffic World (Section 2).

```
:- sorts
  integer;
  node;
  segment;
  car.
```

[3] http://www.cs.utexas.edu/users/tag/cc/traffic.html .

```
:- variables
  Nd                          :: node;
  Sg                          :: segment;
  C,C1                        :: car;
  Ds,Ds1,L                    :: integer;
  Sp,Sp1                      :: integer.

:- objects
  0..maxInt                   :: integer.
```

(Since the range of integers that we need depends on the scenario, we define an appropriate value for the macro `maxInt` in each scenario description.)

```
:- constants
% If a car is pointing toward the end node of the segment on which it
%  currently is, positiveOrientation will be true
  positiveOrientation(car)   ::  inertialFluent;

% Each car has a position at each point in time. The position is
%  indicated as a pair consisting of the segment where the car is
%  located, and the distance travelled along the segment (lmw)

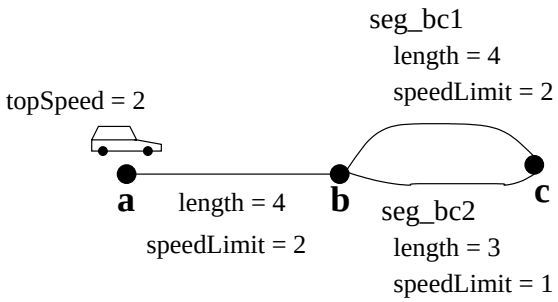

Figure 1: Initial state and landscape for Example 1

7 Examples

We tested certain aspects of our formalization by giving CCALC queries about several scenarios and checking that its answers matched our expectations. Queries related to action domains and their CCALC representations are discussed in [Giunchiglia *et al.*, 2001] (Sections 3.3 and 3.4 and the appendix). Besides the representation of the Traffic World shown above, the input for each scenario included the description of a specific landscape. Here are three examples:

1. Consider 3 roads with the lengths and speed limits shown in Figure 1. The top speed of `car1` *is 2 and it is initially located at node* `a`*. (Note that segment* `seg_bc1` *is long and has a high speed limit whereas segment* `seg_bc2` *is short but its speed limit is low.) Which way must the car go in order to reach* `c` *from* `a` *as soon as possible?*

This planning problem was described as follows:

```
:- query
  maxstep :: 1..10;
  0: position(car1,seg_ab,0),
     positiveOrientation(car1);
  maxstep: node(car1)=c.
```

CCALC found the following plan:

```
0:  node(car1)=a  nextSegment(car1)=none  speed(car1)=2
    distance(car1)=0  segment(car1)=seg_ab

1:  node(car1)=none  nextSegment(car1)=none  speed(car1)=2
    distance(car1)=2  segment(car1)=seg_ab

ACTIONS:  chooseSegment(car1,seg_bc1)
```

```
2:  node(car1)=b  nextSegment(car1)=seg_bc1  speed(car1)=2
    distance(car1)=4  segment(car1)=seg_ab

3:  node(car1)=none  nextSegment(car1)=none  speed(car1)=2
    distance(car1)=2  segment(car1)=seg_bc1

ACTIONS:  chooseSegment(car1,seg_bc2)

4:  node(car1)=c  nextSegment(car1)=seg_bc2  speed(car1)=1
    distance(car1)=4  segment(car1)=seg_bc1
```

2. The top speeds of 3 cars and their initial positions are as shown at the top diagram of Figure 2. Cars `car1`, `car2` *and* `car3` *have top speeds of 3, 2 and 1, respectively. Assuming the speed limit is 3 and the safety distance is 1, how will the cars move during the next 3 time intervals?*

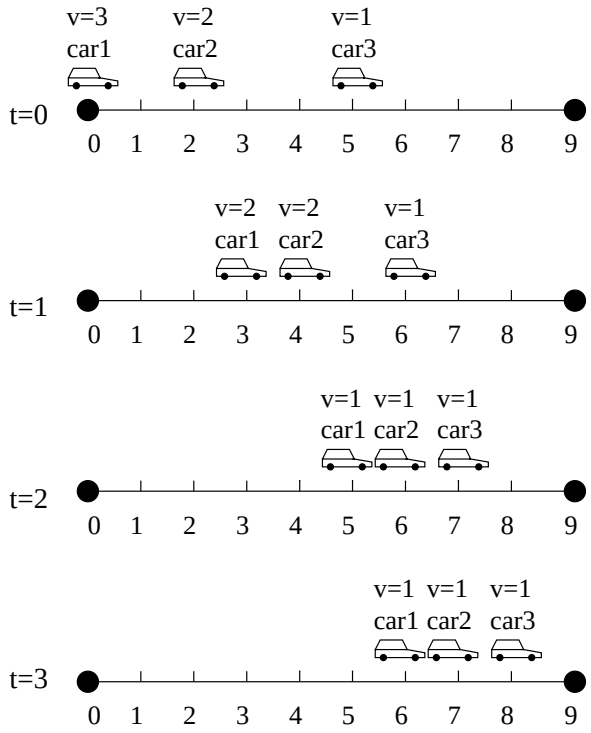

Figure 2: Example 2

The facts in this case were:

```
:- query
  maxstep  :: 3;
  0: position(car1,seg_ab,0),
     positiveOrientation(car1),
     position(car2,seg_ab,2),
     positiveOrientation(car2),
     position(car3,seg_ab,5),
     positiveOrientation(car3).
```

CCALC found a scenario consistent with these facts (Figure 2):

```
0:  speed(car1)=3  speed(car2)=2  speed(car3)=1  distance(car1)=0
    distance(car2)=2  distance(car3)=5

1:  speed(car1)=2  speed(car2)=2  speed(car3)=1  distance(car1)=3
    distance(car2)=4  distance(car3)=6

2:  speed(car1)=1  speed(car2)=1  speed(car3)=1  distance(car1)=5
    distance(car2)=6  distance(car3)=7

3:  speed(car1)=1  speed(car2)=1  speed(car3)=1  distance(car1)=6
    distance(car2)=7  distance(car3)=8
```

3. The landscape and the initial positions of two cars are shown at the top of Figure 3. The top speeds of both cars and the speed limits for all segments are 1. The safety distance is 2. What are the possible scenarios in which both cars will be on segment `seg_cd` *at time 5?*

The facts and goals for this problem were:

```
:- query
  maxstep :: 5;
  0: position(car1,seg_ac,1),
     position(car2,seg_bc,1),
     [/\C | positiveOrientation(C)];
  maxstep: [/\C | segment(C)=seg_cd].
```

CCALC has determined that there are two possibilites. Here is the first (Figure 3):

```
0:  node(car1)=none  node(car2)=none  nextSegment(car1)=none
    nextSegment(car2)=none  speed(car1)=1  speed(car2)=1
    distance(car1)=1  distance(car2)=1  segment(car1)=seg_ac
    segment(car2)=seg_bc
```

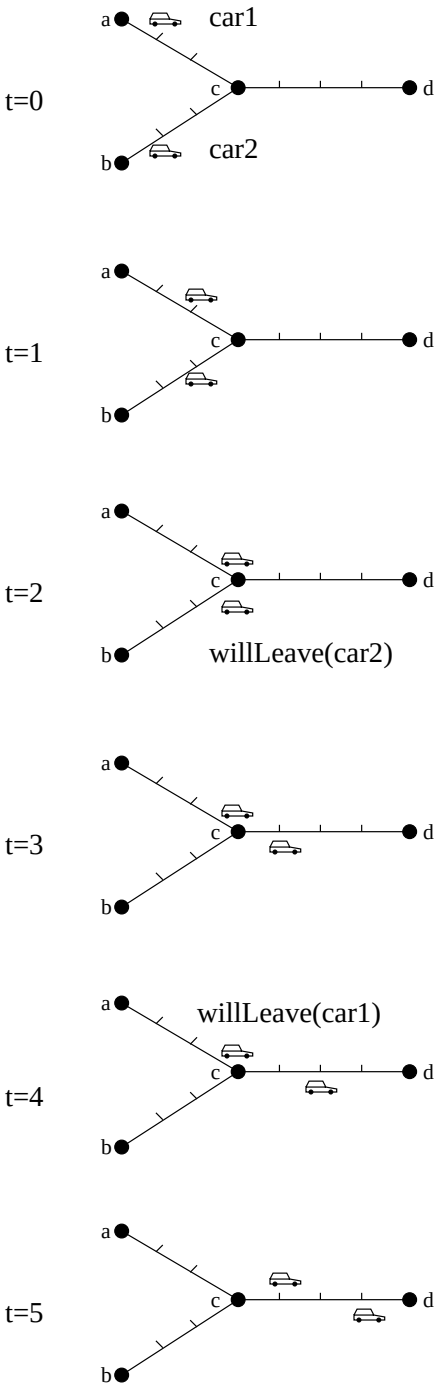

Figure 3: Example 3, Scenario 1

```
1:  node(car1)=none  node(car2)=none  nextSegment(car1)=none
    nextSegment(car2)=none  speed(car1)=1  speed(car2)=1
    distance(car1)=2  distance(car2)=2  segment(car1)=seg_ac
    segment(car2)=seg_bc

ACTIONS:  chooseSegment(car1,seg_cd)  chooseSegment(car2,seg_cd)

2:  node(car1)=c  node(car2)=c  willLeave(car1)
    nextSegment(car1)=seg_cd  nextSegment(car2)=seg_cd
    speed(car1)=1  speed(car2)=0  distance(car1)=3
    distance(car2)=3  segment(car1)=seg_ac  segment(car2)=seg_bc

3:  node(car1)=none  node(car2)=c  nextSegment(car1)=none
    nextSegment(car2)=seg_cd  speed(car1)=1  speed(car2)=0
    distance(car1)=1  distance(car2)=3  segment(car1)=seg_cd
    segment(car2)=seg_bc

4:  node(car1)=none  node(car2)=c  willLeave(car2)
    nextSegment(car1)=none  nextSegment(car2)=seg_cd
    speed(car1)=1  speed(car2)=1  distance(car1)=2
    distance(car2)=3  segment(car1)=seg_cd  segment(car2)=seg_bc

5:  node(car1)=none  node(car2)=none  nextSegment(car1)=none
    nextSegment(car2)=none  speed(car1)=1  speed(car2)=1
    distance(car1)=3  distance(car2)=1  segment(car1)=seg_cd
    segment(car2)=seg_cd
```

In the second scenario, the states at times 0 and 1 and the actions performed between times 1 and 2 are the same. For times 2 through 5, everything is the same except that `car1` is replaced by `car2` everywhere, and vice versa.

The fact that the same actions lead to different states illustrates the nondeterminism in the transition system to which the formalization corresponds. This nondeterminism arises when more than one car is waiting to enter a new segment. In such situations the car which will leave the node is chosen nondeterministically so, as in this example, there may be multiple scenarios that differ from each other by the order of cars leaving the node.

8 Related Work

Henschel and Thielscher [2000] showed how to formalize the Traffic World in the fluent calculus [Thielscher, 1998]. They do not assume that speeds and lengths are expressed

by integers, as we do (Section 3). Other than that, their representation differs from ours in the following ways:

- Instead of having all cars obey the same rules, cars are divided into two groups: "deliberative" cars and "non-deliberative" cars. Drivers of deliberative cars can set their own speeds (using an action to change the speed of a car) instead of having to go at the maximum speed possible, and are allowed to wait at nodes. Non-deliberative cars are just like cars in our paper, as described in the Logic Modelling Workshop specification (Section 2).

- There is a "waiting area" associated with each node-segment pair. In this area, the cars that are going to enter the segment wait in line until there are no cars within *varsigma* from the node. When the new segment becomes free, the first car in the waiting area is allowed to leave.

- At any time, a car is in exactly one of three states: moving on a segment, at a node, or in a waiting area. Cars which are at a node or in a waiting area are not considered to be on segments. So after a car arrives at a node, the cars following it are allowed to arrive at the node too, even if the car remains there.

- For each node, the segments leading to it are assigned priorities. When several drivers simultaneously decide to turn into the same segment, their cars are placed in the waiting area in the order determined by the priorities of the segments they arrived from.

If a car is considered to be on some road segment at all times, as in our formalization, the number of cars that can approach a node is limited by the number of roads leading to that node. The view adopted in [Henschel and Thielscher, 2000], on the other hand, makes a car at a node exempt from the surrounding traffic restriction, so that the number of cars that can gather at a node (or in a waiting area) is unlimited. Perhaps we model streets in a city, and Henschel and Thielscher model roads between towns. It would not be difficult to modify our formalization to include deliberative cars and waiting areas; see [Erdoğan, 2000, Section 5.3] for a related discussion.
